

# Lab 8

## 实验思路

基于Lab 7图算法的基本操作的实现，添加用于查找最大路径的**Bellman-Ford**算法,该算法时间复杂度为 $O(V \cdot E)$

## 代码

```
def PERT(self, topoq):
    lastone=None
    maxlength=0
    topoq[0].d=0
    topoq[0].pre=None
    #更新n-1次
    for i in range(1, len(topoq)):
        for v in topoq :
            for e in self.edges[v]:
                if e[0].d < v.d + e[1]:
                    e[0].d = v.d + e[1]
                    e[0].pre = v
                    if e[0].d > maxlength:
                        lastone = e[0]
                        maxlength = e[0].d

    for v in topoq :
        for e in self.edges[v]:
            if e[0].d < v.d + e[1]:
                return False

    print(maxlength)
    x = lastone
    #根据记录的信息 反推路径
    while x != None:
        print(x.value)
        x = x.pre

    return True
```

# Result

maxlength=18

1> 3> 6> 9> 10

maxlength=8

1> 3> 4> 6

maxlength=27

1> 3> 2> 4> 6

maxlength=16

1> 3> 5> 7> 9
